

Hydraulic Modeling of NRG Energy Center Downtown Minneapolis Chilled Water System

Carl Jauch, NRG Energy Center Minneapolis
Thomas Lund-Hansen, Reliability Efficiency & Optimization

Minneapolis System

Foster House:
2,000 tons, electric

First Avenue:
9,000 tons, steam

Macy's:
2,700 tons, electric

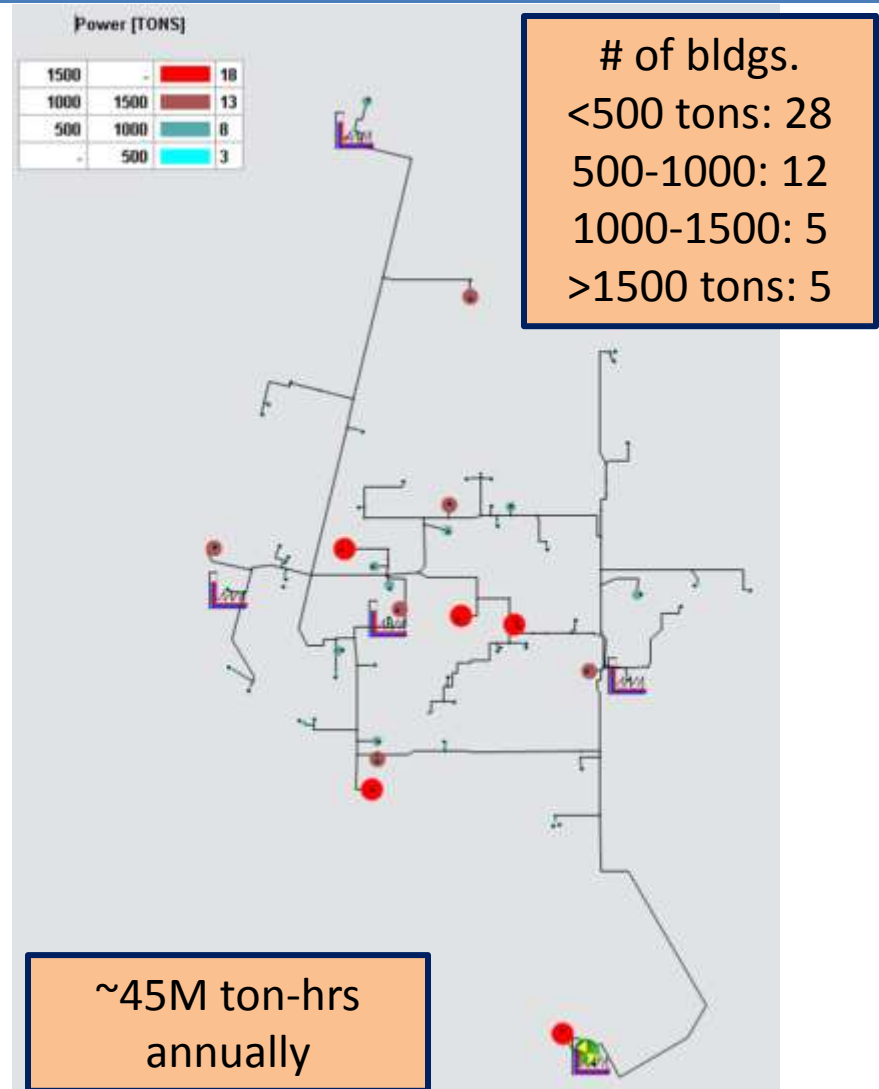

Convention Center:
5,150 tons,
electric/gas

- ***One system in the NRG portfolio***
- ***Operating since 1972, portions date to 1920's***
- ***Capacity: 36,650 tons***
- ***Demand: 27,500 tons***
- ***More than 22 M sq. ft. cooled space***
- ***5 miles direct buried pipe***

Main Plant:
4,000 tons, electric
17,800 tons, steam

Challenges & Need for Modeling

- Competitive market
 - Customer driven
 - Cost/Value
 - NRG initiatives
 - Efficiency & Sustainability
- Complex system
 - Multi-plant, chiller types
 - Broad customer mix
- Tools have to add value
 - Prefer in-house ability
 - Partnership with REO
Termis Solution Providers

Modeling Objectives

- Flow modeling needed to accurately reflect system hydraulics
 - System expansion studies & customer addition studies
 - Evaluate operational flexibility & chiller dispatch
 - Model and quantify cost savings associated with system/operational changes
- Future real-time feedback
 - Chiller dispatch, outage planning, performance feedback, monitoring telemetry
 - Target customers needing assistance to reduce consumption

Termis Modeling

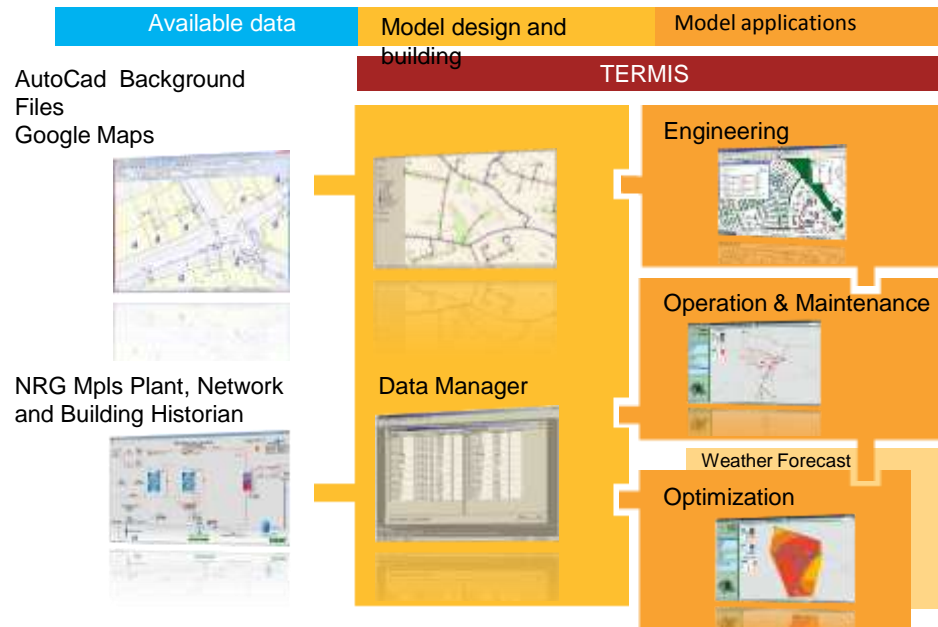

- Definitions/Input:
 - Bldg demand, ΔT
 - Supply temperature
 - Base Pressure
- Results/Output:
 - Plant production
 - System pressures
 - Flow rates
 - Pipe velocities
 - Pressure gradients
 - Temperatures

Modeling Information

- Real-time vs static model
 - “Seeing the world continuously with magnifying glasses vs one or few snapshot views”
- Real-time data import
 - Building usage/loads
 - Plant output and return
- Validation between measurements and predictions
 - Flow, Pressure, ΔP

Real-Time Modeling

Real-Time measurements - about 380 building, network and plant meters/sensors (P,T, Tons and Q among others) - Every 5 minutes import of measurements and simulation

Model Calibration

- Use of Real-Time model

The screenshot shows a software interface for model calibration. It features a table with 17 columns and one data row. The columns are labeled as follows: 1. ID, 2. Scenario, 3. Mea1, 4. Avg. Value [bar], 5. Node1, 6. Avg. Value [bar], 7. Mea2, 8. Avg. Value [bar], 9. Node2, 10. Avg. Value [bar], 11. Distance [m], 12. ΔHead, Mea [Pa], 13. ΔHead, Calc. [Pa], 14. Difference [Pa], 15. Correction Factor [-], 16. Standard Deviation, and 17. Use. The data row contains an asterisk in the ID column, dropdown menus for Scenario and Mea1, and a dropdown menu for Mea2. Below the table is a scrollable area with a vertical scrollbar. At the bottom left, there is a checkbox labeled 'Adjust Factors' with a checkmark (18). At the bottom center, there are three buttons: 'Calculate', 'OK', and 'Cancel'.

1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17
ID	Scenario	Mea1	Avg. Value [bar]	Node1	Avg. Value [bar]	Mea2	Avg. Value [bar]	Node2	Avg. Value [bar]	Distance [m]	ΔHead, Mea [Pa]	ΔHead, Calc. [Pa]	Difference [Pa]	Correction Factor [-]	Standard Deviation	Use
*																

- System Tests

- Plymouth bldg pressure differential doesn't match predictions
- Pipe routing such that valves could be used to flow water via different routes
 - Locate possible source of calibration error

System Expansion Study

- New multi-purpose stadium
 - Have calibrated model to use for studies
 - Allowed system analysis prior to design specific tasks
- Chilled water system impacts
 - Evaluate two possible routes
 - Main plant connection
 - Extension of existing system
 - Assess overall impact on system
 - Plant P limits
 - Bldg P/ Δ P limits
 - Assess operational changes to meet new load
 - Which plants to operate
 - Stadium load variability
 - Provide design input

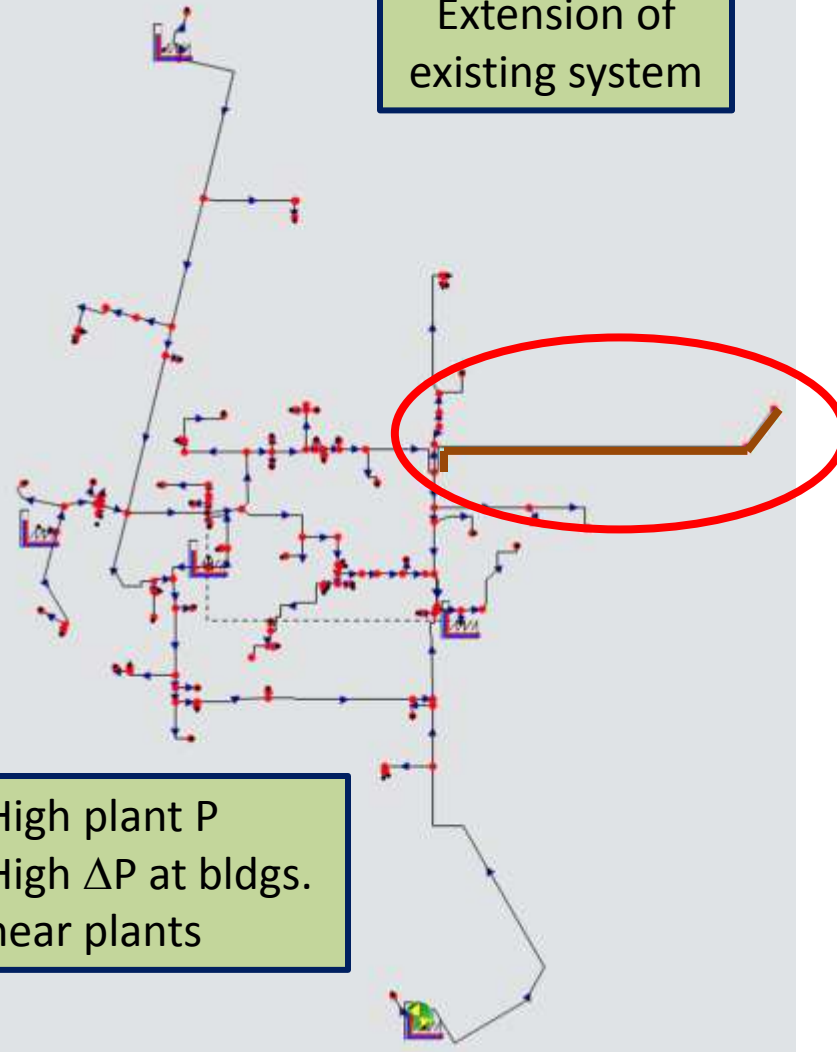

Stadium Supply Routes

New pipe from plant with boost pump

De-couples stadium from system
Two ΔP control points

Extension of existing system

High plant P
High ΔP at bldgs. near plants

Stadium Supply Decisions

- Modeling analysis drove to need to run separate distribution line from main plant to stadium
- Existing piping distribution system has potential choke point which drives overall system pressure too high
- End result is new “east loop” that is somewhat independent of remainder of system
- Boost pump to overcome system losses to stadium
- Need to limit stadium load during normal weekday, can provide excess capacity at night and on weekends

Conclusions and Lessons Learned

- Calibrated model of system complete
 - Real-time and offline model provides understanding of system hydraulics, limitations and bottlenecks
- Model available as engineering design tool for system expansion studies
 - Evaluate operational flexibility and chiller dispatch too
- Moving toward use by Operations and in the Control Room
- Modeling/calibration partnership worked very well
 - In-house knowledge of software and overall system performance is invaluable
 - Allows tighter specifications for design tasks

Thank you!

Abstract

- The NRG Energy Center Minneapolis has developed a hydraulic model of their chilled water distribution system. It is be used for management, operation, engineering and maintenance of the 40,000 tons downtown system. Real-Time hydraulic modeling is a cornerstone of this new platform. This case study includes presentation and demo of the process, results of the work, how NRG has improved decision-making and savings.
